

Numerical Methods I – Problem Set 9

Fall Semester 2005

Due November 23 *in class!*

1. (From SM.) A quadrature formula on the interval $[-1, 1]$ uses the quadrature points $x_0 = -\alpha$ and $x_1 = \alpha$, where $0 < \alpha \leq 1$:

$$\int_{-1}^1 f(x) dx \approx w_0 f(-\alpha) + w_1 f(\alpha).$$

- (a) The formula is required to be exact whenever f is a polynomial of degree 1. Show that $w_0 = w_1 = 1$, independent of the value of α .
- (b) Show that there is one particular value of α for which the formula is exact for all polynomials of degree 2. Find this α , and show that, for this value, the formula is also exact for all polynomials of degree 3.
2. Consider the composite trapezoidal rule for evaluating the integral

$$\int_0^1 x^{1/3} dx.$$

- (a) Show, by explicit evaluation, that the local error on the interval $[0, h]$ is proportional to $h^{4/3}$.
- (b) Show that the global error is also proportional to $h^{4/3}$.
Hint: Use part (a) on the first partition and one of the standard error estimates on all other partitions.
3. **Project:** Use the composite trapezoidal rule with N partitions to approximate the integral of $f(x) = \sinh x$ and $g(x) = \cosh x$ on the interval $[-1, 1]$. As in Lab 7, generate a doubly logarithmic error plot. Which of the functions is integrated more accurately?
4. Explain the behavior seen in the previous question using the Euler–Maclaurin summation formula.

5. **Project:** Use Romberg integration to compute the integral of

$$\begin{aligned} f(x) &= e^x, \\ g(x) &= \sin 2\pi x, \\ h(x) &= x^{1/3} \end{aligned}$$

on the interval $[0, 1]$. Generate a doubly logarithmic error plot and compare with the results from Lab 7.

6. (From SM.) Show that the weights in the Gauss quadrature formula can also be computed via

$$W_k = \int_a^b w(x) L_k(x) dx.$$

Recall: Gauss quadrature is based on the expression

$$\int_a^b w(x) f(x) dx \approx \sum_{k=0}^n W_k f(x_k) + \sum_{k=0}^n V_k f'(x_k),$$

where

$$\begin{aligned} W_k &= \int_a^b w(x) H_k(x) dx, \\ V_k &= \int_a^b w(x) K_k(x) dx, \end{aligned}$$

and where H_k and K_k are the Hermite interpolation basis polynomials, which can be written in terms of the Lagrange interpolation basis polynomials L_k as

$$\begin{aligned} H_k(x) &= L_k^2(x) (1 - 2L_k'(x_k) (x - x_k)), \\ K_k(x) &= L_k^2(x) (x - x_k). \end{aligned}$$

The Gauss quadrature points x_0, \dots, x_n are chosen such that $V_k = 0$ for all $k = 1, \dots, n$.
